Mini Quiz – Climate Change Basics

Focus: Greenhouse Effect · Human Impact · Cause & Effect

Reading Passage:

Climate change refers to long-term shifts in temperatures and weather patterns. While these changes can occur naturally, human activities have rapidly increased the pace of change. Burning fossil fuels such as coal, oil, and natural gas releases carbon dioxide, a gas that traps heat in the atmosphere. The more greenhouse gases we produce, the more heat becomes trapped, leading to global warming. Scientists track these changes to understand how they affect oceans, ecosystems, and human life.

1. What human activity is described as the main driver of climate change?

2. What gas released from burning fossil fuels traps heat in the atmosphere?

3. Explain in one sentence how the greenhouse effect works.

4. Name one way climate change affects ecosystems.

5. Why do scientists monitor temperature and weather patterns over long periods?

Tutoring Tip:

Keep explanations short and clear — focus on the chain: Human Activity → Greenhouse Gases → Warming → Impacts.
