Mini Quiz – Ecosystems Basics

Focus: Biotic & Abiotic · Niches · Food Webs

Reading Passage:

An ecosystem is a community of living organisms interacting with the non-living components of their environment. The living parts, called biotic factors, include plants, animals, fungi, and microorganisms. The non-living parts, or abiotic factors, include sunlight, water, temperature, soil, and air. Each organism plays a role or niche within the ecosystem. Food chains and food webs show how energy moves from producers to consumers and finally to decomposers.

1. What is the difference between biotic and abiotic factors?

2. Give one example of a biotic factor and one abiotic factor.

3. What is a niche?

4. Which organism starts most food chains and why?

5. Why are food webs more realistic than food chains?

Tutoring Tip:

Review examples with students and connect them to real ecosystems like forests, ponds, and grasslands.
