Ecosystems – Home Practice

Focus: Ecosystem Structure · Niches · Food Webs · Energy Flow

Reading Passage:

Ecosystems consist of both living (biotic) and non-living (abiotic) components. The living organisms in an ecosystem, such as plants, animals, and microorganisms, interact with physical factors like sunlight, water, and temperature. Each organism has a specific niche that describes how it obtains food, where it lives, and how it affects the environment. Energy flows through ecosystems from producers to consumers and then to decomposers. Food webs illustrate how these organisms depend on each other, making ecosystems stable and interconnected.

1. List two biotic and two abiotic factors described or implied in the passage.

2. What is a niche? Provide one example from any ecosystem.

3. Explain why producers are essential to all ecosystems.

4. Describe how energy flows from producers to consumers and then to decomposers.

5. Draw or describe a simple 4-step food chain based on the passage.

6. What makes food webs more stable than food chains?

7. Write a 2–3 sentence summary explaining how biotic and abiotic factors interact to create a functioning ecosystem.
